Executive Summary

To commemorate the 10th anniversary of the Nebraska Rural Poll, rural Nebraskans were asked about changes they may have experienced during the past ten years. Where have they lived during the past decade? In what types of business activities have they been involved? Have they received any education or training during that time period? What has been their experience with the Internet?

This report details 2,851 responses to the 2005 Nebraska Rural Poll, the tenth annual effort to understand rural Nebraskans' perceptions. Respondents were asked a series of questions about changes they have experienced during the past ten years. For all questions, comparisons are made among different respondent subgroups, that is, comparisons by age, occupation, region, etc. Based on these analyses, some key findings emerged:

- ***One quarter of rural Nebraskans have lived somewhere other than their current community during the past ten years.*** Of those who have lived elsewhere, they have moved their primary residence an average of 2.2 times.
- ***Younger rural Nebraskans are more likely than older residents to have lived elsewhere during the past decade.*** Sixty-six percent of persons between the ages of 19 and 29 have lived in a different location, compared to only 12 percent of persons age 65 and older.
- ***Many rural Nebraskans who have lived in a different community during the past ten years have lived in another state.*** Forty-one percent of persons who have lived elsewhere during the past decade have lived in a different state. Forty-five percent have lived in a larger community (18% have lived in either Omaha or Lincoln and 27% have lived in or near a Nebraska community larger than their current one - other than Lincoln or Omaha). Thirty-six percent have lived in or near a Nebraska community smaller than their current one.
- ***Twenty percent of rural Nebraskans currently own a business.*** Thirteen percent started operating a business during the past ten years, 10 percent closed or stopped operating a business during this time period and four percent tried unsuccessfully to start a business.
- ***Persons living in or near the smallest communities are more likely than persons living in or near larger communities to currently own a business.*** Twenty-nine percent of persons living in or near communities with less than 500 people currently own a business, compared to 15 percent of persons living in or near communities with at least 10,000 persons.
- ***In general, rural Nebraskans have favorable opinions about self-employment but they also recognize the hardships and risks involved with this type of employment.*** Sixty-one percent agree that self-employment is desirable because they can be their own boss. Forty-four percent agree that self-employment provides a better quality of life than being

an employee. However, 74 percent agree that self-employed individuals work longer hours than traditional employees and 70 percent agree that the cost of health insurance makes self-employment unappealing.

- ***Younger persons are more likely than older persons to agree that the cost of health insurance makes self-employment unappealing.*** Eighty percent of persons age 19 to 29 agree with that statement, compared to 55 percent of persons age 65 and older.
- ***One-half of rural Nebraskans have participated in formal education courses, workshops or other training activities during the past ten years.***
- ***Sixty-nine percent of rural Nebraskans have Internet access either at home or at work.*** Sixty-six percent have acquired Internet access either at home or at work during the past ten years. An additional three percent had acquired access more than ten years ago.
- ***Persons with higher levels of income are more likely than persons with lower incomes to have acquired Internet access.*** Sixty-six percent of persons with household incomes of \$60,000 or more have acquired Internet access at both home and work during the past ten years, compared to only 11 percent of persons with household incomes less than \$20,000.
- ***Information searches and email are the most important reasons for having an Internet connection.*** Eighty-nine percent of rural Nebraskans with access to the Internet at either home or work say that information searches are an important or very important reason for having an Internet connection. Eighty-three percent say email is an important reason.
- ***In general, rural Nebraskans say their satisfaction with various features of their Internet connection has increased during the past ten years.*** Fifty-five percent of rural Nebraskans with an Internet connection at home say their satisfaction with the availability of service has increased during the past ten years and 50 percent report an increase in their satisfaction with the speed of their connection.
- ***Persons living in or near the larger communities are more likely than persons living in or near the smaller communities to say their satisfaction with the speed of their Internet connection has increased during the past ten years.*** Fifty-four percent of persons living in or near communities with populations of 5,000 or more say their satisfaction with the speed of their connection has increased over the past decade, compared to 43 percent of persons living in or near communities with less than 1,000 people.

Introduction

The Nebraska Rural Poll has collected data on the attitudes and opinions of rural Nebraskans over the past ten years. To commemorate the 10th anniversary of the Poll, we decided to find out what changes they have experienced over those years. Where have they lived during the past decade? In what types of business activities have they been involved? Have they received any education or training during that time period? What has been their experience with the Internet? This paper provides a detailed analysis of these questions.

The 2005 Nebraska Rural Poll is the tenth annual effort to understand rural Nebraskans' perceptions. Respondents were asked a series of questions about changes experienced during the past ten years.

Methodology and Respondent Profile

This study is based on 2,851 responses from Nebraskans living in the 84 non-metropolitan counties in the state. A self-administered questionnaire was mailed in February and March to approximately 6,250 randomly selected households.

Metropolitan counties not included in the sample were Cass, Dakota, Dixon, Douglas, Lancaster, Sarpy, Saunders, Seward and Washington. The 14-page questionnaire included questions pertaining to well-being, community, work, the past ten years, housing and alternative energy sources. This paper reports only results from the ten year retrospective portion of the survey.

A 46% response rate was achieved using the total design method (Dillman, 1978). The sequence of steps used follow:

1. A pre-notification letter was sent requesting participation in the study.
2. The questionnaire was mailed with an informal letter signed by the project director approximately seven days later.
3. A reminder postcard was sent to the entire sample approximately seven days after the questionnaire had been sent.
4. Those who had not yet responded within approximately 14 days of the original mailing were sent a replacement questionnaire.

The average respondent is 56 years of age. Seventy-one percent are married (Appendix Table 1¹) and sixty-eight percent live within the city limits of a town or village. On average, respondents have lived in Nebraska 47 years and have lived in their current community 31 years. Fifty-two percent are living in or near towns or villages with populations less than 5,000. Ninety-three percent have attained at least a high school diploma.

Fifty-three percent of the respondents report their 2004 approximate household income from all sources, before taxes, as below \$40,000. Thirty-three percent report incomes over \$50,000.

Seventy percent were employed in 2004 on a full-time, part-time, or seasonal basis. Twenty-five percent are retired. Thirty-four percent of those employed reported working in a professional, technical or administrative occupation. Fourteen percent indicated they were farmers or ranchers. The employed

¹ Appendix Table 1 also includes demographic data from previous rural polls, as well as similar data based on the entire non-metropolitan population of Nebraska (using 2000 U.S. Census data).

respondents who do not work in their home or their nearest community reported having to drive an average of 33 miles, one way, to their primary job.

Mobility During The Past Decade

Twenty-five percent of rural Nebraskans have lived somewhere other than their current community during the past ten years (Figure 1). This question is analyzed by community size, region and various individual attributes (Appendix Table 2).

Residents of the Panhandle are more likely than residents of other regions of the state to have lived elsewhere during the past ten years (see Appendix Figure 1 for the counties included in each region). Thirty percent of the Panhandle residents have lived in a different community during the past ten years, compared to 20 percent of the residents of the Northeast region.

Younger residents are much more likely than older residents to have lived elsewhere during the past decade. Sixty-six percent of persons between the ages of 19 and 29 have lived in a different location, compared to only 12 percent of persons age 65 and older (Figure 2).

Similarly, persons who have never married are more likely than other marital groups to have lived in a different location during the past decade. Forty-two percent of persons who have never married have lived elsewhere during the past decade, compared to only 15 percent of widowed respondents.

The other groups most likely to have lived in a different community include: females, persons with the highest education levels and persons with either sales or professional occupations.

Of those respondents who have lived elsewhere during the past ten years, they have moved their primary residence an average of 2.2 times. Forty-three percent moved their primary residence once, while two percent did not move their primary residence at all during the past ten years. Fourteen percent moved their primary residence four or more times.

The frequency of moves differs by community size, age, gender, marital status and education (Appendix Table 2). The

youngest respondents are more frequent movers as compared to the older respondents. Thirty-five percent of persons age 19 to 29 have moved their primary residence four or more times during the past decade, compared to only six percent of persons age 65 and older. Other groups most likely to have moved four or more times include: residents living in or near communities with populations ranging from 500 to 999 as well as persons living in the largest communities (populations of 10,000 or more), females, persons who have never married and respondents with some college education.

The respondents who have lived in another location were also asked where they lived during the past ten years. Many rural Nebraskans (41%) have lived in another state during the past decade (Figure 3). Thirty-six percent have lived in or near a Nebraska community smaller than their current one, 27 percent have lived in or near a Nebraska community larger than their current one (other than Lincoln or Omaha) and 18 percent have lived in the Omaha or Lincoln metropolitan areas.

The locations in which people have lived differ by some of the characteristics examined (Appendix Table 2). As expected, residents of smaller communities are more likely than residents of larger communities to have lived in a Nebraska community larger than their current one. Similarly, residents of larger communities are more likely than those living in smaller communities to have lived in a Nebraska community smaller than their current one.

Residents of both the Northeast and South Central regions are more likely than persons living in other regions of the state to have

lived in a Nebraska community smaller than their current one. Approximately 41 percent of the movers in these two regions have lived in a smaller Nebraska community during the past decade, compared to 23 percent of the movers in the Panhandle.

Persons with higher household incomes are more likely than persons with lower incomes to have lived in the Omaha or Lincoln metropolitan areas during the past decade. Twenty-eight percent of the movers with household incomes of \$60,000 or more have lived in the Omaha or Lincoln area, compared to 12 percent of the movers with household incomes under \$20,000 who have lived in the state's metropolitan areas.

Younger persons are more likely than older persons to have lived in both the Omaha or Lincoln areas as well as in or near a

Nebraska community larger than their current one. Males are more likely than females to have lived in a Nebraska community larger than their current one (30 percent compared to 22 percent). Females are more likely than males to have lived in a Nebraska community smaller than their current one (42 percent compared to 33 percent).

Persons who have never married are more likely than other marital groups to have lived in the Omaha or Lincoln metropolitan areas during the past ten years. Twenty-seven percent of this group have lived in the metropolitan areas, compared to only three percent of widowed respondents.

When comparing responses by education, persons with at least a bachelor's degree are more likely than persons with less education to have lived in the Omaha or Lincoln areas. Twenty-seven percent of movers with at least an undergraduate degree have lived in one of the state's two largest cities, compared to eight percent of the persons with a high school education or less. Those with some college (two year or no degree) are the group most likely to have lived in a Nebraska community larger than their current one.

There was only one interesting finding related to occupation. Persons with sales occupations are more likely than persons with different occupations to have lived in the Omaha or Lincoln areas during the past decade. Thirty-two percent of the movers with sales occupations have lived in the state's metropolitan areas, compared to only eight percent of the workers with service occupations.

Business Activities During the Past Decade

Small businesses are very important to the economies of rural Nebraska communities. Thus, respondents were asked what business activities they or anyone in their household have been involved in during the past ten years.

Twenty percent of rural Nebraskans currently own a business and 13 percent started operating a business during the past ten years (Figure 4). Ten percent closed or stopped operating a business during this time frame and four percent attempted to start a business but were unsuccessful.

Business activities differ by many of the characteristics examined (Appendix Table 3). Residents of the smallest communities are more likely than residents of larger communities to have attempted to start a business during the past ten years but were unsuccessful. Seven percent of persons

living in or near communities with less than 500 people tried unsuccessfully to start a business, compared to three percent of persons living in or near communities with populations ranging from 500 to 999. The residents of the smallest communities are also the community size group most likely to currently own a business. Twenty-nine percent of persons living in or near communities with less than 500 people currently own a business, compared to 15 percent of persons living in or near communities with at least 10,000 people.

Persons living in the Panhandle are more likely than persons living in other regions of the state to have tried unsuccessfully to start a business during the past decade. Seven percent of the Panhandle residents tried to start a business but were unsuccessful. This compares to three percent of the residents of both the North Central and Northeast regions.

Persons with the highest household incomes are more likely than persons with lower incomes to both have started a business during this time as well as currently own a business. Twenty-six percent of persons with household incomes of \$60,000 or more currently own a business, compared to 16 percent of persons with incomes under \$20,000.

Younger respondents are more likely than older respondents to have started operating a business during the past ten years as well as to have tried unsuccessfully to start a business. However, older respondents are more likely than younger respondents to have closed or stopped operating a business during this time frame. Persons between the ages of 40 and 49 are the group most likely to currently own a business (28 percent

compared to 14 percent of persons age 65 and older).

Males are more likely than females to have done the following business activities during the past decade: started operating a business (14 percent compared to 9 percent), closed or stopped operating a business (11 percent and 7 percent) and currently own a business (23 percent compared to 15 percent).

Married respondents are the marital group most likely to have done three of these activities: started operating a business, closed or stopped operating a business and currently own a business. However, divorced/separated respondents are the marital group most likely to have tried unsuccessfully during the past ten years to start a business.

Persons with at least some college education are more likely than persons without any college education to have started operating a business during the past ten years as well as currently own a business. Persons with only some college education (two year or no degree) are the group most likely to have attempted to start a business but were unsuccessful.

Persons with sales occupations are more likely than persons with different occupations to both have started operating a business during the past ten years as well as to have stopped operating or closed a business during this time. Persons with administrative support positions are the occupation group most likely to have tried unsuccessfully to start a business (10 percent compared to two percent of farmers and ranchers). Farmers and ranchers are the occupation group most likely to currently own a business. Forty-seven percent of

farmers or ranchers currently own a business compared to nine percent of persons with administrative support positions.

To further examine rural Nebraskans' entrepreneurial spirit, they were asked their opinions about self-employment. Generally, they appear to like the idea of self-employment but are also aware of the risks involved with this type of employment. Sixty-one percent agree or strongly agree that "self-employment is desirable to me because I can be my own boss" (Table 1). Forty-four percent agree that "self-employment provides a better quality of life than being an employee." However, they also believe that self-employment requires a large time commitment and worry about how to obtain health insurance. Seventy-four percent agree that "self-

employed individuals work longer hours than traditional employees." In addition, 70 percent agree with the statement "the cost of health insurance makes self-employment unappealing."

Thirty-eight percent agree that "self-employment is unappealing to me because of financial risks." But, 33 percent either strongly disagree or disagree with the statement. When asked about job security, 26 percent agree that "the self-employed have more job security than traditional employees." However, 45 percent disagree with that statement.

These opinions about self-employment are examined by community size, region and various individual attributes (Appendix Table 4). Many differences are detected.

Table 1. Opinions Regarding Self-Employment

	<i>Strongly Disagree</i>	<i>Disagree</i>	<i>No Opinion</i>	<i>Agree</i>	<i>Strongly Agree</i>
Self-employment is desirable to me because I can be my own boss.	3%	10%	26%	39%	22%
Self-employment is unappealing to me because of financial risks.	7	26	30	31	7
Self-employment provides a better quality of life than being an employee.	3	19	35	33	11
Self-employed individuals work longer hours than traditional employees.	1	6	19	48	26
The self-employed have more job security than traditional employees.	6	39	29	21	5
The cost of health insurance makes self-employment unappealing.	3	7	20	41	29

Residents of smaller communities are more likely than residents of the larger communities to have favorable opinions about self-employment. The smaller community residents are more likely than residents of larger communities to agree with the following statements: self-employment is desirable to me because I can be my own boss; self-employment provides a better quality of life than being an employee and the self-employed have more job security than traditional employees. And, they are more likely to disagree with the statement that self-employment is unappealing to me because of financial risks. Forty percent of persons living in or near communities with less than 500 people disagreed or strongly disagreed with that statement, compared to 28 percent of persons living in or near communities with populations of 10,000 or more. However, residents of smaller communities are also the group most likely to agree that self-employed individuals work longer hours than traditional employees.

Only one difference occurs by region. Residents of the South Central region are more likely than residents of other regions to agree that self-employment is unappealing to them because of financial risks. Forty-one percent of the residents of the South Central region agree with that statement, compared to 31 percent of the residents of the North Central region.

Persons with the highest household incomes are more likely than persons with lower incomes to agree that self-employment is desirable to them because they can be their own boss. However, they are also more likely than persons with lower incomes to agree that self-employed individuals work longer hours than traditional employees and that the cost of health insurance makes self-employment unappealing. They are also the group most likely to disagree that self-employment provides a better quality of life

than being an employee. Persons with the lowest incomes are the group most likely to agree that the self-employed have more job security than traditional employees. When asked if self-employment is unappealing because of financial risks, persons with incomes ranging from \$20,000 to \$59,999 are the group most likely to agree.

The youngest respondents are the age group most likely to agree that self-employment is desirable because they can be their own boss. However, they also have reservations about this type of employment. Persons age 19 to 39 are the age group most likely to agree that self-employment is unappealing because of financial risks and persons age 19 to 29 are the group most likely to agree that the cost of health insurance makes self-employment unappealing. Eighty percent of persons age 19 to 29 agree that the cost of health insurance makes self-employment unappealing, compared to 55 percent of persons age 65 and older (Figure 5). Persons between the ages of 30 and 64 are the group most likely to agree that self-employment

provides a better quality of life than being an employee. Persons between the ages of 40 and 64 are the group most likely to agree that self-employed individuals work longer hours. The oldest respondents (age 65 and older) are the group most likely to agree that the self-employed have more job security than traditional employees.

Males are more likely than females to have positive views about self-employment. They are more likely than females to agree with the following: self-employment is desirable because I can be my own boss; self-employment provides a better quality of life than being an employee; and the self-employed have more job security than traditional employees. And, they are more likely than females to disagree that the cost of health insurance makes self-employment unappealing. But, they are also more likely than females to agree that self-employed individuals work longer hours than traditional employees. Females are more likely than males to agree that self-employment is unappealing because of financial risks.

Persons with the highest levels of education are more likely than persons with less education to agree that self-employment is desirable because they can be their own boss and that self-employed individuals work longer hours than traditional employees. Persons with some college education are the group most likely to agree with the following statements: self-employment is unappealing because of financial risks; self-employment provides a better quality of life than being an employee; and the cost of health insurance makes self-employment unappealing. Persons with the least amount of education are the group most likely to agree that the self-employed have more job security than traditional employees.

When comparing marital groups, married

respondents appear to have the most positive outlook on self-employment. They are the marital group most likely to believe that self-employment is desirable so they can be their own boss and that self-employment provides a better quality of life and more job security. Married persons are also the marital group most likely to believe that self-employed individuals work longer hours than traditional employees. Persons who have never married are the marital group most likely to agree that self-employment is unappealing because of financial risks. And, the divorced/separated respondents are the marital group most likely to agree that the cost of health insurance makes self-employment unappealing.

Farmers and ranchers are the occupation group most likely to have a positive view of self-employment. They are the occupation group most likely to agree that self-employment is desirable to be their own boss and that self-employment provides a better quality of life and more job security. But, farmers and ranchers are also most likely to agree that self-employed individuals work longer hours. Persons with administrative support positions are the group most likely to agree that self-employment is unappealing because of financial risks.

Education or Training During the Past Decade

One-half (50%) of rural Nebraskans have participated in formal education courses, workshops or other training activities during the past ten years (Figure 6). Some differences are detected when comparing responses by community size, region and various individual attributes (Appendix Table 5).

Persons living in or near the largest communities are more likely than persons living in or near the smallest communities to have participated in education activities during the

Figure 6. Have you participated in any formal education courses, workshops or other training activities during the past 10 years?

past ten years. Fifty-five percent of persons living in or near communities with populations of 10,000 or more have participated in education activities, compared to 45 percent of persons living in or near communities with less than 500 people.

Other groups most likely to have participated in education courses, workshops or other training include: persons with the highest household incomes, the youngest respondents, persons who have never married, persons with the highest

education levels and persons with professional occupations.

Persons who have participated in any education activity during the past ten years were then asked in which types they had participated. Seventy-eight percent of the persons participating in any education activity have participated in seminars or workshops for their job (Figure 7). Forty-three percent have participated in courses for continuing education units and 37 percent took seminars or workshops for their own general interest.

The types of education activities taken are examined by community size, region and various individual attributes (Appendix Table 5). Persons living in or near the smallest communities are more likely than persons living in or near larger communities to have taken seminars or workshops for their own general interest. Forty-six percent of persons living in or near communities with less than 500 persons had taken these seminars or workshops during

Figure 7. Types of Education Activities Participated in During Past Ten Years

the past ten years, compared to 32 percent of persons living in or near communities with populations of 10,000 or more.

Persons with the highest household incomes are more likely than persons with lower incomes to have taken courses to complete or count toward a masters or other advanced degree, courses for continuing education units, and seminars or workshops for their job. Persons with lower incomes are more likely than persons with higher incomes to have taken courses to complete or count toward an associate degree.

Females are more likely than males to have taken courses to complete or count toward a bachelors degree and non-credit courses for their own general interest. Males are more likely than females to have taken courses to complete or count toward a certification program and seminars or workshops for their job.

The youngest persons are more likely than older persons to have taken courses to complete or count toward both an associate degree and a bachelors degree. Persons between the ages of 30 and 39 are the group most likely to have taken courses to complete or count toward a masters or other advanced degree. Persons between the ages of 40 and 49 are the group most likely to have taken courses to complete or count toward a certification program. Persons between the ages of 40 and 64 are the group most likely to have taken courses for continuing education units and seminars or workshops for their job. The oldest respondents (age 65 and older) are more likely than younger respondents to have taken non-credit courses for their own general interest and seminars or workshops for their own general interest.

Persons who have never married are the marital group most likely to have taken courses to

complete or count toward both an associate and bachelors degree. Married respondents are the group most likely to have taken courses for continuing education units. Both married and divorced/separated respondents are the groups most likely to have taken seminars or workshops for their job. Both non-credit courses as well as seminars or workshops for their own general interest are more likely to be taken by widowed respondents as compared to the other marital groups.

Persons with the highest education levels are more likely than persons with less education to have taken courses to complete or count toward both a bachelors and masters or other advanced degree as well as courses for continuing education units. Persons with some college are the education group most likely to have taken courses to complete or count toward an associate degree.

Persons with professional occupations are more likely than persons with different occupations to have taken courses to complete or count toward a masters or other advanced degree and courses for continuing education units. They are also, along with the manual laborers, most likely to have taken seminars or workshops for their job. Farmers and ranchers are the occupation group most likely to have taken seminars or workshops for their own general interest.

Internet Access During the Past Decade

The final questions in this section ask respondents about their experience with the Internet during the past decade. Sixty-six percent of rural Nebraskans have acquired Internet access during the past ten years (Figure 8). Another three percent had acquired Internet access more than ten years ago. Thus, 69 percent of rural Nebraskans have Internet access.

Responses to this question are analyzed by community size, region and various individual attributes (Appendix Table 6). Persons living in or near the largest communities are more likely than persons living in or near the smaller communities to have Internet access at both their home and at work. Forty-two percent of respondents living in or near communities with populations of 10,000 or more acquired Internet access at both their home and work in the past ten years, compared to 28 percent of persons living in or near communities with less than 500 people.

Persons living in the Panhandle are more likely than persons living in other regions of the state to have Internet access. Seventy-five percent of persons living in the Panhandle have Internet access, compared to 66 percent of persons living in either the North Central or Southeast regions of the state.

Persons with the highest levels of income are more likely than persons with lower incomes to have acquired Internet access at both their home

and at work (Figure 9). Sixty-six percent of persons with household incomes of \$60,000 or more have acquired Internet access at both home and work during the past ten years, compared to only 11 percent of persons with household incomes less than \$20,000.

Younger respondents are more likely than older respondents to have acquired Internet access. Eighty-nine percent of persons age 19 to 49 have acquired Internet access, compared to only 40 percent of persons age 65 and older.

Males are more likely than females to have acquired Internet access at home only and at both home and work. Females are more likely than males to have Internet access at work only.

Widowed respondents are the marital group *least* likely to have Internet access. Only 30 percent of widowed respondents have acquired Internet access, compared to 76 percent of

married respondents. Married respondents are the marital group most likely to have access at their home only and at both home and work.

Over one-half (52%) of persons with a high school diploma or no diploma do not have Internet access. Persons with at least a bachelor's degree are the education group most likely to have access at both home and work and to have acquired Internet access more than ten years ago.

Persons with administrative support positions are the occupation group most likely to have Internet access at work only. Manual laborers and farmers and ranchers are the occupation groups most likely to only have access at home, while persons with professional occupations are most likely to have it at both home and work.

Respondents with Internet access were next asked how they primarily connect to the Internet both at home and at work. Thirty percent connect to the Internet at work via DSL and 19 percent connect using a dial-up modem. The proportions using other types of connections are as follows: cable modem (17%), don't know (15%), wireless (9%), other (6%), and satellite (4%).

Dial-up modems are the most common type of Internet connection used at home (58%). The same proportions (18%) use both DSL and cable modems to connect to the Internet. Other connections include: wireless (3%), satellite (1%), don't know (1%) and other (1%).

The types of Internet connections used are examined by community size, region and individual attributes (Appendix Table 7). Persons living in or near the smallest communities are more likely than persons living in or near larger communities to use a dial-up modem at work. Persons living in the larger

communities are more likely than persons living in the smaller communities to use a cable modem connection at work.

At home, persons living in or near the smallest communities are the group most likely to use either a dial-up modem or DSL. Persons living in or near the largest communities are the group most likely to use a cable modem to connect to the Internet.

When examining differences by income, persons with lower incomes are more likely than persons with higher incomes to use a dial-up modem at work, while the persons with higher incomes are more likely to use a DSL connection. A similar pattern is found when examining their home connections. Households with lower incomes are the income group most likely to use a dial-up modem, whereas the higher income households are most likely to use either DSL or a cable modem.

Females are more likely than males to not know what type of Internet connection they use at work. Males are more likely than females to use both a dial-up modem and a cable modem to connect to the Internet at work.

The oldest respondents are more likely than younger respondents to use a dial-up modem to connect to the Internet at both work and their home. Seventy-three percent of persons age 65 and older use a dial-up modem to connect to the Internet at home, compared to 51 percent of persons age 19 to 29. Younger persons are more likely than older persons to use DSL to connect to the Internet at both home and work. They are also the age group most likely to connect to the Internet at home using a cable modem.

Persons with less education are more likely than persons with more education to use a dial-up

modem to connect to the Internet at work. Persons with higher education levels are the group most likely to use DSL or another type of connection at work.

Farmers and ranchers are the occupation group most likely to use a dial-up modem to connect to the Internet both at work and at home. Seventy-four percent of farmers and ranchers connect to the Internet at home using a dial-up modem, compared to only 49 percent of persons with administrative support positions.

Respondents were next asked how important various reasons are to their household for having an Internet connection. Information searches and email are the top two reasons given for having an Internet connection (based on the proportion saying they are either important or very important) (Figure 10). Playing games had the lowest proportion saying it was an important reason (23%).

The responses to this question are analyzed by community size, region and various individual attributes (Appendix Table 8). Persons living in or near the smaller communities are more likely

than persons living in or near the larger communities to say that both work or business and school work are important reasons for having an Internet connection. Sixty-eight percent of persons living in or near communities with less than 1,000 people say that work or business is an important reason for having an Internet connection, compared to 55 percent of persons living in or near communities with populations ranging from 5,000 to 9,999. Persons living in or near the larger communities are more likely than persons living in or near the smaller communities to say online banking/financial transactions is an important reason.

Persons with higher household incomes are more likely than persons with lower incomes to say the following reasons are important: for work or business, school work, online purchases, information searches, and online banking/financial transactions. Persons with the lowest household incomes are the group most likely to say playing games is an important reason.

Younger respondents are more likely than older respondents to say the following reasons are

important for having an Internet connection: for work or business, school work, online purchases, information searches, and online banking/financial transactions. The oldest respondents (age 65 and older) are the age group most likely to say playing games is an important reason for having an Internet connection.

Females are more likely than males to say email and playing games are important reasons for having an Internet connection. Persons with the highest education levels are more likely than persons with less education to say the following reasons are important: for work or business, email, school work, online purchases, information searches, and online banking/financial transactions. Persons with the least amount of education are the group most likely to say playing games is an important reason for having an Internet connection.

Married respondents are the marital group most likely to say work or business and school work are important reasons for having an Internet connection. Persons who have never married are the group most likely to say online purchases is an important reason.

Manual laborers are the occupation group most likely to say playing games and school work are important reasons for having an Internet connection. Both persons with sales and professional occupations are the groups most likely to say work or business is an important reason. Online banking/financial transactions was most important to the persons with sales occupations, whereas email was most important to both those with professional and administrative support positions.

Finally, respondents were asked how their satisfaction with various items related to their Internet connection have changed during the

past ten years. In general, rural Nebraskans tend to say their satisfaction has increased with each item. At least one-half say their satisfaction has increased or greatly increased with the availability of service (55%) and speed of connection (50%) (Figure 11).

Their change in satisfaction with these items are examined by community size, region and various individual attributes (Appendix Table 9). Persons living in or near the larger communities are more likely than persons living in or near the smaller communities to say their satisfaction with both the dependability of service and the speed of connection has increased during the past ten years. Fifty-four percent of persons living in or near communities with populations of 5,000 or more say their satisfaction with the speed of connection has increased during the past ten years, compared to 43 percent of persons living in or near communities with less than 1,000 people (Figure 12).

Persons living in the North Central region are

Figure 12. *Change in Satisfaction with Internet Connection Speed Over Past 10 Years by Community Size*

more likely than persons living in other regions of the state to say their satisfaction with dependability of service has increased over the past ten years. Fifty-three percent of the North Central residents say their satisfaction with the dependability of their service has increased, compared to 44 percent of the Panhandle residents. The residents of the North Central region are also the group most likely to report an increase in their satisfaction with special features during the past ten years.

Persons with higher household incomes are more likely than persons with lower incomes to report an increase in their satisfaction with the following: availability of service, dependability of service and speed of connection.

Younger respondents are more likely than older respondents to say their satisfaction with availability of Internet service has increased during the past ten years. Persons between the ages of 30 and 39 are the age group most likely to report an increase in satisfaction with the following: dependability of service, speed of

connection and special features. Persons between the ages of 50 and 64 are the age group most likely to say their satisfaction with cost has increased during the past ten years.

Males are more likely than females to report an increase in satisfaction with the cost of their Internet service during the past decade. Persons with higher education levels are more likely than persons with less education to have increased their satisfaction with each item listed.

Persons with sales occupations are more likely than persons with different occupations to report an increase in satisfaction with cost, dependability of service and connection speed during the past ten years. Persons with administrative support positions are the occupation group most likely to have increased their satisfaction with availability of service and dependability of service.

Conclusion

Rural Nebraskans have been fairly mobile during the past ten years. One-quarter have lived in a different community during the past decade. Younger Nebraskans, though, have been much more mobile. Approximately two-thirds (66%) of persons age 19 to 29 have lived in a different community in the last ten years. Many of those individuals lived in a community larger than their current one. Thus, we see a pattern opposite that of the “brain drain,” a term commonly used to describe the notion that youth are leaving our rural areas. Younger people are locating in rural Nebraska and many have done so after experiencing life in a larger community.

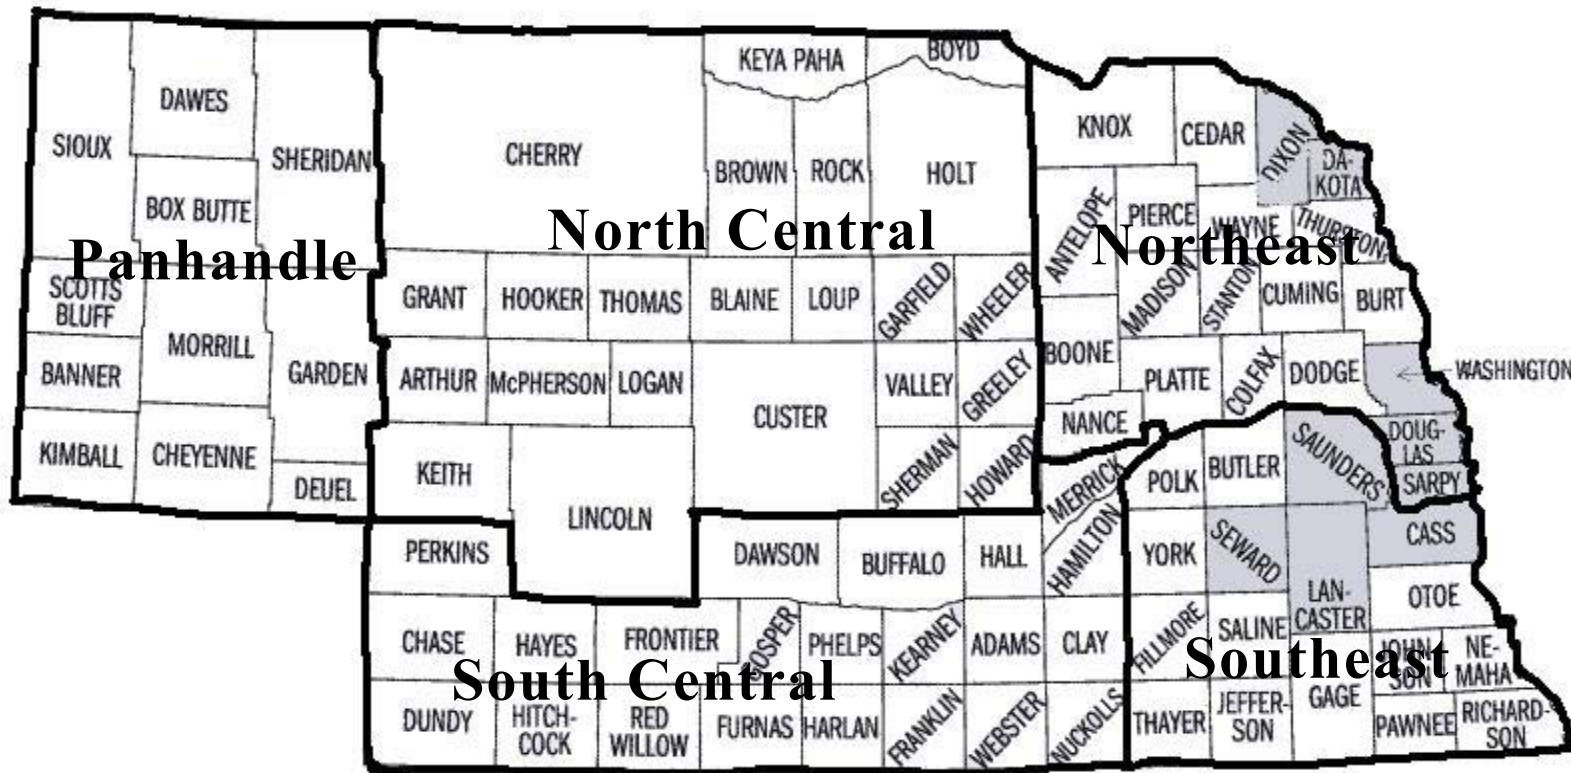

Many rural Nebraskans have also been involved in various business activities during the past decade. Twenty percent of rural Nebraskan

households currently own a business. Business ownership is more common in smaller communities than in larger ones. Many rural Nebraskans also have favorable views about self-employment. Most agree that self-employment is appealing because they can be their own boss. However, they also recognize the risks and hardships that this type of employment can bring. One particular obstacle to self-employment is the cost of health insurance. The majority of rural Nebraskans say the cost of health insurance makes self-employment unappealing to them. This was especially true of younger persons. They are more likely than older people to express wariness of the financial risks of self-employment as well as the cost of health insurance. This is an area that must be addressed if we are to encourage business ownership among the younger generation.

Many rural Nebraskans are life-long learners. One-half of the respondents have taken some type of educational activity during the past ten years. Already a highly educated population, rural Nebraskans continue to improve their skills and knowledge through education and training.

Many rural Nebraskans also have access to the Internet, either at home or at work. However, there appears to be several sub-groups of the population that do not have access: persons with lower incomes, older persons and people with lower education levels. We are not sure if it is due to a lack of access to this technology or simply because of a lack of interest. But, this is an area that should be explored further.
